

Ecological condition and the recommended Red List of the Criş/Körös¹ river system

Andrei Sárkány-Kiss & Kunigunda Macalik

Abstract

This concluding study analyses the ecological condition of the river system. Its statements are based on the statements of the authors of this book. Although the polluted sections are not very long, the ecological condition and the living organisms of these rivers are endangered by the seriously high content of xenobiotics. The hydrotechnical works have a negative effect on the quality of the water. The red list concerns only the Criş/Körös Basin. In this Basin there are a lot of valuable areas which should be protected.

Keywords: Criş/Körös Rivers, ecological condition, Red List.

Discussion

The statements of this concluding study are based on the statements of the authors of this book, and the red list was accomplished according to their suggestions, too.

The condition of the river system (Crişul Alb/Fehér-Körös, Crişul Negru/Fekete-Körös, Crişul Repede/Sebes-Körös and Barcău/Berettyó) rivers is relatively good compared to other Transylvanian rivers. The observed pollution are not causing spectacular changes, only on some short sections of the rivers. On the lower reach of the three Criş/Körös rivers we identified associations and species whose presence indicate to fairly good water quality. For example, in all the three Criş/Körös rivers the presence of the Plecoptera, Ephemeroptera and *Bivalvia* fauna is significant.

Only on the 1st site the Crişul Alb/Fehér-Körös river can be considered as being in a natural state. This fact is supported by the studies from this book. On the 2nd sampling site the dam constructions at Mihăileni caused significant changes. On the 3rd site (downstream at Brad) a great influence of the drainage and the waste-water can be noticed.

1 The first name is Romanian, and the second Hungarian.

These two human effects break the continuous areal of such sensitive species like the Plecoptera, Ephemeroptera species and *Ancylus fluviatilis* snail. The abundance of the Oligochaeta species is considerably high, as the consequence of the sediments rich in organic matter. Due to the natural clearing, the condition of the river is getting better before the 5th site (Almaş); this is why the *Ancylus fluviatilis* snail reappears. It is only from the 5th site that we could find the Unionida shells, although the 3rd and the 4th sites could well be suitable for their spreading; it is quite probable that they had stocked this reach in the past. On the middle and lower reach of the river the wooded territories are few, the river is bordered with agricultural land; so the river is affected by antropogenous influences. On the lower reach of the river the sensitive shell and fish species are present, but their heavy metal content is very high, this endangers their survival. Because of the heavy metal content we classified them into the "vulnerable" category of the red list. Before the 6th sampling site a dam tightens the river-bed down to Gyula (14th site). The dam is very close to the river-bed, thus the river ceases to have a flood area. During the regulation of the river-ways the bends were cut through, and because of this the overall view of the river resembles a canal. On the plain the slow water-run of the river creates favourable states for the eutrophication.

The Crişul Negru/Fekete Körös, like the Crişul Alb is undisturbed only at its spring area (8th site). At Ștei (9 site) residual and waste-waters flow into the river, and drastically change the biocenosis. At the 8th site the rare Plecoptera and Ephemeroptera species and the *Ancylus fluviatilis* snail are still present. They have disappeared from site 9. The Trichoptera species, belonging to the Hydropsychidae family, and the less sensitive Ephemeroptera species have survived. At this site, as the water is polluted with organic matters, the Oligochaeta species have the highest abundance, especially the Limnodrilus hoffmeisteri and the Tubifex tubifex, the latter appearing only here and being present in a high number. At Borz (10th site) we observed higher diversity. The benthonic fauna is made up of Ephemeroptera, Odonata and Trichoptera species. Similarly, the diversity of the zooplankton is due to the better water quality. It is here that the unionid shells appear for the first time. The appearance of the submerged macrovegetation is indicated by the high trophic level. Besides the biological epuration of the waters, this relatively better condition due to a strong physico-chemical clearing, since in the Borz Straight the river has a faster water run and becomes richer in oxygen. At Tinca (11th site) the slower run of the river places down more and more sediments and organic matters, this is relevant by the benthonic fauna and by the content of the zooplankton: the diversity is lower. The zoobenthon is made up mostly by filtering organisms like Unionida, Tricophtera, which have great influence in the natural purification. The slow run of the river and the thicker sediment is due to the extreme growth of the submerged vegetation. At Zerind (site 12) and at Gyula (site 14) the associations indicate a slow and eutrophic water; this can be noticed especially in the composition of the zooplankton and the macrophyta vegetation. This reach of the Crişul Negru, like the Crişul Alb is canalised and straightened within a dam-system.

The upper stream of the Crișul Repede/Sebes Körös (from Șaula to the inflow of the Drăgan stream) has a very slow run. From the marsh springs it carries much organic matters and deposes a thick muddy sediment in this slightly sloping river-bed. Organisms typical to the hilly section stock the river. After the inflow of the Drăgan stream the Crișul Repede runs down on a steeper slope, and before the Criș Strait the Iad stream joins in. Here the Plecoptera, Ephemeroptera, Trichoptera and Gastropoda species begin to appear, which are typical to mountain region. From time to time the Iad stream comes rushing into the Crișul Repede with a great amount of cold water, which is absolutely damaging to the benthonic fauna and for the fish fauna. In the Vadu Crișului defile among the limestone rocks the river runs down in a steep slope, the water speed reaches 1,5 m/sec. Although the water is clean and rich in oxygen, the Plecoptera and Ephemeroptera species, which are typical to mountain region, are missing. This fact is probably due to the deep (sometimes 1,5 m) and fast running water. From the defile to the Aleșd locality the river condition is good, it is stocked by species characteristic to a submountain region. At Aleșd the organic matter load is growing, and the human influence is strong, due to the water-supply engineering works on the river. Between Aleșd and Oradea two dams have been built and the third is being constructed now right before Oradea. The constructions completely the river-bed, between the two dams the water runs in cemented canals, which is absolutely unfavourable for the living organisms that assure the natural purification. In the completed dam-lakes the deposition of the sediment has started and the first living organism characteristic to lake environment have appeared, for example the *Anodonta cygnea*. On this reach it is in the old river-bed that we found the most varied benthonic fauna; but this is endangered, because the water is directed to a new, cemented river-bed. At Fughiu sampling site the river-bed preserves its natural state, but water-supply engineering works are in process near the river. Here too the riverside groves are missing, and agricultural territories surround the river-bed. Downstream to Oradea at Cheresig site the industrial (this city has a highly developed chemical industry) and the household waste-water, as well as the pollution of the stock-raising farms leave their marks on the river biocenosis. While taking the samples, we found dead shells which indicate poor water quality. On the plain region to Szeghalom the eutrophication process is going on; this fact is proved by the greenish colour of the water and by the presence of many aquatic weeds.

The river-head of the Barcău/Berettyó river is on a hilly region, its water has a very good quality, it is rich in trout (*Salmo trutta fario*) to Boghiș sampling site. It can be stated that the river is very polluted starting from the region of Suplacu de Barcău, where the oil-pollution resulting from oil production was very significant, especially in 1994. Similarly, at Sântimreu we still could not find more exigent benthonic species except some Odonata species; but the quality of the water is improving after the oil-polluted section. This fact is proved by the presence of the *Sphaerium rivicola* species. The oil-pollution has not taken place without any consequences. It is very likely that from this river the following fish species have died out: *Leuciscus leuciscus*, *Gobio kessleri*, *Sabanejewia aurata* and *Gymnocephalus schraetseri*. On the Hungarian section of the river Berettyó, at Szeghalom,

the water has a very slow run, the presence of the weeds in a large number indicates a high trophic level, and the river is stocked by Gastropoda species, typical to still waters. We got ascertained of the fact that in this river the *Anodonta cygnea* existed in the recent past, because we found the shells of younger and older samples with unharmed ligament; but we couldn't identify living individs. During the research the iridescent oil layer came to the water surface from the disturbed sediment.

The speed of the Kettős-Körös and Hármas-Körös rivers, pressed between dam-system, is very slow. The slow water, together with a high organic and nutritive content, favours the eutrophication. The high level of eutrophication is also indicated by the high content of chlorophyll-a of the water.

Final conclusions

In the Criș/Körös Basin on the middle and lower reach of the studied rivers we found significant human influences which have three main sources:

1. The absence of the contiguous forests and the extensive agriculture strongly affect the rivers.
2. The hydrotechnical works (barrages, dam-systems and dam-lakes and the river regulation in general) have a negative effect on the quality of the water.
3. The industrial and the household waste-water is rather significant in several sections. Some elements of the fauna are endangered by a seriously high content of xenobiontics.
4. In the Basin of the Criș/Körös Rivers there are a lot of important areas which should be protected, such as: Vadu Crișului Strait, thermal springs at Răbăgani and Băile Episcopești, Cefa fish ponds and Rădvani wood.

Acknowledgments

We wish to thank all the specialists of the Criș/Körös team for providing information and thus making possible the compilation of this red list. We would also like to express our gratitude to the ornithologists Mr. Dan Munteanu and Mr. Zoltán Szombath for their critical advice in this respect.

The recommended Red List of the Criș/Körös Rivers Basin

The following red list has been compiled on basis of the suggestions of this volume's authors, according to the IUCN categorisation. We are aware of the fact that this list is not complete, and that the included species reveal only the momentary condition of the research. However, we do hope that this red list will serve as the basis of a new and more elaborate list.

This red list concerns only the Criș/Körös rivers Basin.

Ex = disappeared; cited in the bibliography or make part of a collection, but not found during the last 50 years.

Pisces

Gobio kessleri Dybows. (Barcău)

Lota lota L. (Barcău)

Aves

Gyps fulvus (Habl.)

Ex? = not found again during the research

Macrophyta

Acorus calamus L.

Aldrovanda vesiculosa L.

Andromeda polifolia L.

Betula pubescens Ehrh.

Carex appropinquata Schumacher

Carex lasiocarpa Ehrh.

Cladium mariscus (L.) Pohl.

Drosera rotundifolia L.

Marsilia quadrifolia L.

Ophioglossum vulgatum L.

Rhynchospora alba (L.) Vahl.
